

FACTS ABOUT

SUSTAINABILITY OF MAN-MADE FIBRES (#MMF)

- Oil-based feedstock used in European production of MMF amounts to less than 0.1 % of world oil production
- Many MMF are produced from **renewable natural resources** such as trees
- Use of **recycled materials** as a raw material source for **MMF** is large and growing, including factory waste, PET plastic bottles, fishing nets, carpets, and other types of postconsumer waste from textiles and other sectors
- A small but growing proportion of MMF production is based on innovative raw material sources such as corn or vegetable oil, and may move to biomass in future

- Production facilities occupy little land and use very little water compared with alternative natural fibres requiring large quantities for irrigation and processing - no fertilizers and pesticides
- A large proportion of man-made fibres is **dyed or delustered during the production process**, avoiding the need for water and energy-intensive dyeing at a later stage
- Desirable characteristics such as flame retardancy, antimicrobial and anti-odour properties can be permanently built in during production and inherently embedded in the fibre, avoiding the use of resource-intensive processing at a later stage and emissions to the environment from textile article treatments, and introducing less dermal contact of surface-applied substances

FACTS About MMF

RECYCLABLE BIODEGRADABLE DURABLE LIGHT IN WEIGHT REDUCING CO2 EMISSIONS REDUCING WATER USE REDUCING ENERGY CONSUMPTION VERSATILE INDISPENSABLE

- Certain types of MMF are biodegradable
- Concentration on production efficiency and quality by European MMF manufacturers is very high, resulting in a great reduction of waste during processing
- **MMF** are **easy to recycle** through mechanical recycling, chemical recycling and glycolisis
- If necessary, textile waste which cannot be recycled (including post-consumer waste) can be efficiently incinerated with electricity and heat recovery, because of the high calorific value of MMF

- Most **MMF** can be processed at **lower temperatures** than alternative materials, with large energy savings
- All European MMF producers respect strict European, national and local limits on water and air emissions, on employee exposure levels and on chemical safety (under REACH) – European regulations are among the strictest in the world
- All European MMF producers have invested heavily to cut their energy consumption, thereby considerably reducing carbon emissions

- MMF are durable, and can be developed for even higher durability at an acceptable cost, giving longer product life to apparel and household textiles, and a wide variety of technical uses
- **MMF** are **light in weight** and can be efficiently packed, allowing savings on resource use and transport costs
- MMF can be laundered at low temperatures, with large energy savings
- Ultra-high strength MMF such as carbon fibres can replace other much heavier materials such as steel
- MMF reinforcement of composites allows dramatic weight savings in aircraft, cars, trains, wind turbines, and containers

- MMF play an essential role in geotextiles for flood prevention, land slides and civil engineering projects
- MMF in agrotextiles help to protect food crops from adverse weather conditions, increasing yields and reducing food spoilage
- MMF are necessary in filtration to remove pollutants from air and water emissions
- MMF in medical textiles can accelerate the healing process (wounding, fixation) and are used in hygiene in a wide area of medical environments
